ABSTRACT

These notes provide a detailed derivation of series formula for (i) Meridian distance \( M \) as a function of latitude \( \phi \) and the ellipsoid constant eccentricity-squared \( e^2 \), and \( \phi \) and the ellipsoid constant third flattening \( n \); (ii) Rectifying latitude \( \mu \) as functions of \( \phi, e^2 \) and \( \phi, n \); and (iii) latitude \( \phi \) as functions of \( \mu, e^2 \) and \( \mu, n \). These series can then be used in solving the direct and inverse problems on the ellipsoid (using great elliptic arcs) and are easily obtained using the Computer Algebra System Maxima.

In addition, a detailed derivation of the equation for the great elliptic arc on an ellipsoid is provided as well as defining the azimuth and the vertex of a great elliptic. And to assist in the solution of the direct and inverse problems the auxiliary sphere is introduced and equations developed.

INTRODUCTION

In geodesy, the great elliptic arc between \( P_1 \) and \( P_2 \) on the ellipsoid is the curve created by intersecting the ellipsoid with the plane containing \( P_1, P_2 \) and \( O \) (the centre of the ellipsoid) and these planes are great elliptic planes or sections. Figure 1 shows \( P \) on the great elliptic arc between \( P_1 \) and \( P_2 \). \( \theta_p \) is the geocentric latitude of \( P \) and \( \lambda_p \) is the longitude of \( P \).

There are an infinite number of planes that cut the surface of the ellipsoid and contain the chord \( P_1P_2 \) but only one of these will contain the centre \( O \). Two other planes are the normal section plane \( P_1P_2 \) (containing the normal at \( P_1 \)) and the normal section plane \( P_2P_1 \).

---

1 This paper follows on from an earlier paper The Great Elliptic Arc on an Ellipsoid and is the result of work done for a review of a paper titled The General Solutions for Great Ellipse on the Spheroid by Wei-Kuo Tseng (Department of Merchant Marine, National Taiwan Ocean University). The methods and equations developed here follow Tseng (in part) and others mentioned in the References.
(containing the normal at $P_2$). All of these curves of intersection (including the great elliptic arc and the two normal section curves) are plane curves that are arcs of ellipses (for a proof of this see Deakin & Hunter, 2010a).

![Diagram of great elliptic arc on ellipsoid](image)

**Figure 1: Great elliptic arc on ellipsoid**

All meridians of longitude on an ellipsoid and the ellipsoid equator are great elliptic arcs. Parallels of latitude – excepting the equator – are not great elliptic arcs. So we could say that the great elliptic arc is a unique plane curve on the ellipsoid – since it is created by the single plane containing $P_1$, $P_2$ and $O$. But it is not the shortest distance between $P_1$ and $P_2$; this unique property (shortest length) belongs to the geodesic.

Great elliptic arcs are seldom used in geodesy as they don't have a practical connection with theodolite observations made on the surface of the earth that are approximated as observations made on an ellipsoid; e.g., normal section curves and curves of alignment. Nor are they the shortest distance between points on the ellipsoid; but, if we ignore earth rotation, they are the curves traced out on the geocentric ellipsoid by the ground point of an earth orbiting satellite or a ballistic missile moving in an orbital plane containing the earth's centre of mass. Here geocentric means $O$ (the centre of the ellipsoid) is coincident with the centre of mass.

The series that we will develop are based on meridian distance $M$; the distance along the arc of a meridian from the equator to the point of latitude $\phi$ and meridian distances are identical to distances from $E$ on the equator to $P_1$ and $P_2$ on the great elliptic (Figure 1).
Every great elliptic section intersects the equatorial plane of the ellipsoid along a line of intersection passing the centre $O$, and the equator at $E$ and $E'$ that are ‘nodes’ of the great elliptic. The line $EE' = 2a$ is the major axis of the great elliptic. Every great elliptic will have two vertices $V$ and $V'$ (north and south of the equator) where a point moving along the great elliptic will attain a maximum latitude and the line $VV' = 2b'$ is the minor axis of the great elliptic; perpendicular to $EE'$ and passing through $O$ (note that $V'$ is not shown in Figure 1 and that $OV = b'$ is the semi-minor axis of the great elliptic). The meridian passing through the vertex will be advanced $90^\circ$ in longitude from the meridian passing through the node; i.e., $\lambda_v - \lambda_e = 90^\circ$ and we will show how the latitude and longitude of the vertex can be obtained from the equation of the great elliptic plane. Knowing these relationships is the key to solving the direct and inverse problems of the great elliptic arc on the ellipsoid where the direct problem is: given latitude and longitude of $P_1$ and the azimuth $\alpha_{12}$ and distance $s$ to $P_2$; compute the latitude and longitude of $P_2$ and the reverse azimuth $\alpha_{21}$. The inverse problem is: given the latitudes and longitudes of $P_1$ and $P_2$; compute the forward and reverse azimuths $\alpha_{12}$, $\alpha_{21}$ and the great elliptic arc distance $s$.

Before proceeding, some definitions of terms relating to the ellipsoid (and including a definition the ellipsoid itself) will be useful

**Ellipsoid**

The ellipsoid is a surface of revolution created by rotating an ellipse (whose semi-axes are $a$ and $b$ and $a > b$) about its minor axis. It is the mathematical approximation of the earth and has geometric constants: flattening $f$; third flattening $n$; eccentricity $e$; second eccentricity $e'$ and polar radius of curvature $c$ given by

$$f = \frac{a-b}{a} \quad (1)$$

$$n = a - b = \frac{f}{2 - f} = \frac{1 - \sqrt{1 - e^2}}{1 + \sqrt{1 - e^2}} = \frac{\sqrt{1 + e'^2} - 1}{\sqrt{1 + e'^2} + 1} \quad (2)$$

$$e'^2 = \frac{a^2 - b^2}{a^2} = \frac{e'^2}{1 + e'^2} = f \left(2 - f\right) = \frac{4n}{(1 + n)^2} \quad (3)$$

$$e'^2 = \frac{a^2 - b^2}{b^2} = \frac{e^2}{1 - e^2} = \frac{f \left(2 - f\right)}{(1 - f)^2} = \frac{4n}{(1 - n)^2} \quad (4)$$
The ellipsoid radii of curvature \( \rho \) (meridian plane) and \( \nu \) (prime vertical plane) at a point whose latitude is \( \phi \) are (Deakin & Hunter 2010a)

\[
\rho = \frac{a(1 - e^2)}{(1 - e^2 \sin^2 \phi)^{3/2}} = \frac{c}{W^3} \quad \text{and} \quad \nu = \frac{a}{(1 - e^2 \sin^2 \phi)^{1/2}} = \frac{c}{V}
\]

where latitude functions \( V \) and \( W \) are

\[
W^2 = 1 - e^2 \sin^2 \phi; \quad V^2 = 1 + e'^2 \cos^2 \phi = \frac{1 + n^2 + 2n \cos 2\phi}{(1 - n)^2} \quad \text{and} \quad W = \frac{b}{a} V
\]

**Meridian distance \( M \)**

Meridian distance \( M \) is defined as the arc of the meridian ellipse from the equator to the point of latitude \( \phi \) (in Figure 1 the meridian distance of \( P \) is the arc \( FP \))

\[
M = \int_0^\phi \rho \, d\phi = \int_0^\phi \frac{a(1 - e^2)}{W^3} \, d\phi = \int_0^\phi \frac{c}{V^3} \, d\phi
\]

This is an elliptic integral that cannot be expressed in terms of elementary functions; instead, the integrand is expanded by into a series using Taylor’s theorem (see Appendix 2) then evaluated by term-by-term integration. The usual form of the series formula for \( M \) is a function of \( \phi \) and powers of \( e^2 \) obtained from (Deakin & Hunter 2010a)

\[
M = a \left(1 - e^2\right) \int_0^\phi \left(1 - e^2 \sin^2 \phi\right)^{3/2} \, d\phi
\]

But the German geodesist F.R. Helmert (1880) gave a formula for meridian distance as a function of \( \phi \) and powers of \( n \) that required fewer terms for the same accuracy. Helmert’s method of development is given in Deakin & Hunter (2010a) and with some algebra we may write

\[
M = \frac{a}{1 + n} \int_0^\phi (1 - n^2)^2 \left(1 + n^2 + 2n \cos 2\phi\right)^{-3/2} \, d\phi
\]

We will show, using Maxima, that (9) and (10) can easily be evaluated and \( M \) written as

\[
M = a \left(1 - e^2\right) \left\{ b_0 \phi + b_2 \sin 2\phi + b_4 \sin 4\phi + b_6 \sin 6\phi + b_8 \sin 8\phi + b_{10} \sin 10\phi + \cdots \right\}
\]

where the coefficients \( \left\{ b_n \right\} \) are to order \( e^{10} \) as follows
\[ b_0 = 1 + \frac{3}{4} \epsilon^2 + \frac{45}{64} \epsilon^4 + \frac{175}{256} \epsilon^6 + \frac{11025}{16384} \epsilon^8 + \frac{43659}{65536} \epsilon^{10} + \ldots \]

\[ b_2 = \frac{3}{8} \epsilon^2 - \frac{15}{32} \epsilon^4 - \frac{525}{1024} \epsilon^6 - \frac{2205}{4096} \epsilon^8 - \frac{72765}{131072} \epsilon^{10} - \ldots \]

\[ b_4 = \frac{15}{256} \epsilon^4 + \frac{105}{1024} \epsilon^6 + \frac{2205}{16384} \epsilon^8 + \frac{10395}{65536} \epsilon^{10} + \ldots \]

\[ b_6 = -\frac{35}{3072} \epsilon^6 - \frac{105}{315} \epsilon^8 - \frac{10395}{3465} \epsilon^{10} - \ldots \]

\[ b_8 = \frac{315}{131072} \epsilon^8 + \frac{524288}{693} \epsilon^{10} + \ldots \]

\[ b_{10} = -\frac{693}{1310720} \epsilon^{10} - \ldots \]  

or

\[ M = \frac{a}{1 + n} \left\{ c_0 \phi + c_2 \sin 2\phi + c_4 \sin 4\phi + c_6 \sin 6\phi + c_8 \sin 8\phi + c_{10} \sin 10\phi + \ldots \right\} \]  

(13)

where the coefficients \( \{c_n\} \) are to order \( n^5 \) as follows

\[ c_0 = 1 + \frac{1}{4} n^2 + \frac{1}{64} n^4 + \cdots \]

\[ c_2 = -\frac{3}{2} n + \frac{3}{16} n^3 + \frac{3}{128} n^5 + \cdots \]

\[ c_4 = \frac{15}{16} n^2 - \frac{15}{64} n^4 + \cdots \]

\[ c_6 = -\frac{35}{48} n^3 + \frac{175}{768} n^5 + \cdots \]

\[ c_8 = \frac{315}{512} n^4 + \cdots \]

\[ c_{10} = -\frac{693}{1280} n^5 + \cdots \]  

(14)

Note here that for WGS84 ellipsoid (the reference ellipsoid of the World Geodetic System 1984) where \( a = 6378137 \, \text{m} \) and \( f = 1/298.257223563 \) the ellipsoid constants

\[ n = 1.679220386383705e - 003 \quad \text{and} \quad \epsilon^2 = 6.694379990141317e - 003 \], and \( n^5 \approx \frac{\epsilon^{10}}{1007} \approx \frac{\epsilon^{12}}{6.7} \).

This demonstrates that the series (13) with fewer terms in the coefficients \( \{c_n\} \) is at least as ‘accurate’ as the series (11). To test this consider the meridian distance expressed as a sum of terms \( M = M_0 + M_2 + M_4 + \cdots \) where for series (11) \( M_0 = a \left( 1 - \epsilon^2 \right) b_0 \phi \), \( M_2 = a \left( 1 - \epsilon^2 \right) b_2 \sin 2\phi \), \( M_4 = a \left( 1 - \epsilon^2 \right) b_4 \sin 4\phi \), etc. and for series (13) \( M_0 = \frac{a}{1 + n} c_0 \phi \), \( M_2 = \frac{a}{1 + n} c_2 \sin 2\phi \), \( M_4 = \frac{a}{1 + n} c_4 \sin 4\phi \), etc. Maximum values for \( M_0, M_2, M_4, \cdots \) occur at latitudes \( \phi = 90^\circ, 45^\circ, 22.5^\circ, \ldots \) when \( \phi = \text{max} \) or \( \sin k\phi = 1 \) and testing the differences between terms at these maximums revealed no differences greater than 0.5 micrometres.

So series (13) should be the preferable method of computation. Indeed, further truncation of the coefficients \( \{c_n\} \) to order \( n^4 \) and truncating series (13) at \( c_8 \sin 8\phi \) revealed no differences greater than 1 micrometre.
Quadrant length $Q$

The quadrant length of the ellipsoid $Q$ is the length of the meridian arc from the equator to the pole and is obtained from equation (11) by setting $\phi = \frac{1}{2} \pi$, and noting that
\[
\sin 2\phi, \sin 4\phi, \sin 6\phi, \ldots \text{ all equal zero, giving}
\]
\[
Q = a \left(1 - e^2\right) b_0 \frac{\pi}{2}
\]
\[
= a \left(1 - e^2\right) \left[1 + \frac{3}{4} e^2 + \frac{45}{64} e^4 + \frac{175}{256} e^6 + \frac{11025}{16384} e^8 + \frac{43659}{65536} e^{10} + \ldots\right] \frac{\pi}{2}
\]
(15)

Similarly, using equation (13)
\[
Q = \frac{a}{1 + n} c_0 \frac{\pi}{2} = \frac{a}{1 + n} \left[1 + \frac{1}{4} n^2 + \frac{1}{64} n^4 + \ldots\right] \frac{\pi}{2}
\]
(16)

Rectifying latitude $\mu$ and rectifying radius $A$

If the meridian distance $M$ on the ellipsoid is equivalent to a meridian distance (great circle arc) on a (rectifying) sphere of radius $A$ then the rectifying latitude $\mu$ is defined by
\[
M = A \mu
\]
(17)

An expression for $A$ is obtained by considering the case when $\mu = \frac{1}{2} \pi$ and $M$ is equal to the quadrant distance $Q$ and (17) may be rearranged to give $A = 2Q/\pi$ and then using (15) to give $A$ to order $e^{10}$ as
\[
A = a \left(1 - e^2\right) b_0
\]
\[
= a \left(1 - e^2\right) \left[1 + \frac{3}{4} e^2 + \frac{45}{64} e^4 + \frac{175}{256} e^6 + \frac{11025}{16384} e^8 + \frac{43659}{65536} e^{10} + \ldots\right]
\]
(18)

Similarly, using (16)
\[
A = \frac{a}{1 + n} \left[1 + \frac{1}{4} n^2 + \frac{1}{64} n^4 + \ldots\right]
\]
(19)

Re-arranging (17) and using (11) and (18) gives the rectifying latitude as
\[
\mu = \frac{M}{A} = \phi + \left(b_z/b_0\right) \sin 2\phi + \left(b_4/b_0\right) \sin 4\phi + \left(b_6/b_0\right) \sin 6\phi + \cdots
\]
(20)

or
\[
\mu = \phi + g_2 \sin 2\phi + g_4 \sin 4\phi + g_6 \sin 6\phi + g_8 \sin 8\phi + g_{10} \sin 10\phi + \cdots
\]
(21)

where the coefficients $\left\{g_n = b_n/b_0\right\}$ are to order $e^{10}$.
Similarly, we may obtain

$$\mu = \phi + d_2 \sin 2\phi + d_4 \sin 4\phi + d_6 \sin 6\phi + d_8 \sin 8\phi + d_{10} \sin 10\phi + \cdots$$  \hspace{1cm} (23)$$

where the coefficients \( \{d_n\} \) are to order \( n^5 \) as follows

\[
d_2 = -\frac{3}{2} n + \frac{9}{16} n^3 - \frac{3}{32} n^5 + \cdots \quad d_4 = \frac{15}{2} n^2 - \frac{15}{32} n^4 + \cdots \quad d_6 = -\frac{35}{48} n^3 + \frac{105}{256} n^5 - \cdots \quad d_8 = \frac{315}{512} n^4 - \cdots \quad d_{10} = -\frac{693}{1280} n^5 + \cdots
\]  \hspace{1cm} (24)

Maxima can easily perform the algebra required for (21) and (23) by using a Taylor series representation of \( b_0^{-1} \) for the ‘e-series’ and \( c_0^{-1} \) for the ‘n-series’.

**Latitude \( \phi \) as a function of rectifying latitude \( \mu \)**

An expression for \( \phi \) as a function of \( \mu \) and powers of \( e \) is obtained by reversion of series (21) using Lagrange’s theorem (see Appendix 3) giving

$$\phi = \mu + G_2 \sin 2\mu + G_4 \sin 4\mu + G_6 \sin 6\mu + G_8 \sin 8\mu + G_{10} \sin 10\mu + \cdots$$  \hspace{1cm} (25)$$

where the coefficients \( \{G_n\} \) are to order \( e^{10} \) as follows

\[
G_2 = \frac{3}{8} e^2 + \frac{3}{16} e^4 + \frac{213}{2048} e^6 + \frac{255}{4096} e^8 + \frac{20861}{524288} e^{10} + \cdots \\
G_4 = \frac{21}{256} e^4 + \frac{21}{256} e^6 + \frac{533}{8192} e^8 + \frac{197}{4096} e^{10} + \cdots \\
G_6 = \frac{151}{6144} e^6 + \frac{151}{4096} e^8 + \frac{5019}{131072} e^{10} + \cdots \\
G_8 = \frac{1097}{65536} e^8 + \frac{1097}{131072} e^{10} + \cdots \\
G_{10} = \frac{8011}{2621440} e^{10} + \cdots
\]  \hspace{1cm} (26)

Similarly, reversion of series (23) gives

$$\phi = \mu + D_2 \sin 2\mu + D_4 \sin 4\mu + D_6 \sin 6\mu + D_8 \sin 8\mu + D_{10} \sin 10\mu + \cdots$$  \hspace{1cm} (27)$$

where the coefficients \( \{D_n\} \) are to order \( n^5 \) as follows
\[ D_2 = \frac{3}{2} n - \frac{27}{32} n^3 + \frac{269}{512} n^5 - \cdots \quad D_4 = \frac{21}{16} n^2 - \frac{55}{32} n^4 + \cdots \quad D_6 = \frac{151}{96} n^3 - \frac{417}{128} n^5 + \cdots \] (28)

\[ D_8 = \frac{1097}{512} n^4 - \cdots \quad D_{10} = \frac{8011}{2560} n^5 - \cdots \]

Again, Maxima can easily perform the calculus and algebra required to obtain ‘e-series’ (25) or ‘n-series’ (27) using Lagrange’s theorem.

The series developed above can be used in the direct and inverse problems on the ellipsoid using the great elliptic arc.

**EQUATION OF A GREAT ELLIPTIC ARC SECTION**

Figure 1 shows \( P \) on the great elliptic arc that passes through \( P_1 \) and \( P_2 \) on the ellipsoid. Parallels of latitude \( \phi \) and meridians of longitude \( \lambda \) have their respective reference planes; the equator and the Greenwich meridian, and longitudes are measured 0° to ±180° (east positive, west negative) from the Greenwich meridian and latitudes are measured 0° to ±90° (north positive, south negative) from the equator. The \( x,y,z \) geocentric Cartesian coordinate system has an origin at \( O \), the centre of the ellipsoid, and the \( z \)-axis is the minor axis (axis of revolution). The \( xOz \) plane is the Greenwich meridian plane (the origin of longitudes) and the \( xOy \) plane is the equatorial plane. The positive \( x \)-axis passes through the intersection of the Greenwich meridian and the equator, the positive \( y \)-axis is advanced 90° east along the equator and the positive \( z \)-axis passes through the north pole of the ellipsoid.

In Figure 1, \( \theta_p \) is the geocentric latitude of \( P \) and (geodetic) latitude \( \phi \) and geocentric latitude \( \theta \) are related by

\[ \tan \theta = \left(1 - e^2\right) \tan \phi = \frac{b^2}{a^2} \tan \phi = \left(1 - f\right)^2 \tan \phi \] (29)

The geometric relationship between geocentric latitude \( \theta \) and (geodetic) latitude \( \phi \) is shown in Figure 2, noting that the normal to the ellipsoid does not pass through the centre \( O \) but instead cuts the rotation axis of the ellipsoid at \( H \) and the distance \( OH = \nu e^2 \sin \phi \) and \( \nu = PH \) is the radius of curvature in the prime vertical plane.
The distance $r = OP$ will be useful and is given by the polar equation for an ellipse as

$$r = \frac{ab}{\sqrt{a^2 \sin^2 \theta + b^2 \cos^2 \theta}}$$

(30)

And after some algebra and the use of equations (3) and (4) we may obtain

$$r = \frac{b}{\sqrt{1 - e^2 \cos^2 \theta}} = \frac{a}{\sqrt{1 + e^2 \sin^2 \theta}}$$

(31)

The great elliptic plane in Figure 1 is defined by points $\odot$, $\ominus$ and $\ominus$ that are $P_1$, $P_2$ and the centre of the ellipsoid $O$ respectively. Cartesian coordinates of $\odot$ and $\ominus$ are computed from the following equations

$$x = \nu \cos \phi \cos \lambda = \frac{c}{V} \cos \phi \cos \lambda = r \cos \theta \cos \lambda$$

$$y = \nu \cos \phi \sin \lambda = \frac{c}{V} \cos \phi \sin \lambda = r \cos \theta \sin \lambda$$

$$z = \nu (1 - e^2) \sin \phi = \frac{b}{V} \sin \phi = r \sin \theta$$

(32)

The Cartesian coordinates of point $\ominus$ are all zero.

The general equation of a plane may be written as

$$Ax + By + Cz + D = 0$$

(33)

And the equation of the plane passing through points $\odot$, $\ominus$ and $\ominus$ is given in the form of a 3rd-order determinant

$$\begin{vmatrix}
    x - x_1 & y - y_1 & z - z_1 \\
    x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\
    x_3 - x_2 & y_3 - y_2 & z_3 - z_2 \\
\end{vmatrix} = 0$$

(34)
or expanded into 2nd-order determinants

\[
\begin{vmatrix}
    y_2 - y_1 & z_2 - z_1 \\
    y_3 - y_2 & z_3 - z_2 \\
\end{vmatrix}
(x - x_1) - \begin{vmatrix}
    x_2 - x_1 & z_2 - z_1 \\
    x_3 - x_2 & z_3 - z_2 \\
\end{vmatrix}
(y - y_1) + \begin{vmatrix}
    x_2 - x_1 & y_2 - y_1 \\
    x_3 - x_2 & y_3 - y_2 \\
\end{vmatrix}
(z - z_1) = 0 \quad (35)
\]

Expanding the determinants in equation (35) gives

\[
\left(x - x_1\right) \left\{ \left(y_2 - y_1\right) \left(z_3 - z_2\right) - \left(z_2 - z_1\right) \left(y_3 - y_2\right) \right\} \\
- \left(y - y_1\right) \left\{ \left(x_2 - x_1\right) \left(z_3 - z_2\right) - \left(z_2 - z_1\right) \left(x_3 - x_2\right) \right\} \\
+ \left(z - z_1\right) \left\{ \left(x_2 - x_1\right) \left(y_3 - y_2\right) - \left(y_2 - y_1\right) \left(x_3 - x_2\right) \right\} = 0 \quad (36)
\]

Now since \( x_3 = y_3 = z_3 = 0 \) equation (36) becomes

\[
\left(x - x_1\right) \left\{ \left(y_2 - y_1\right) \left(-z_2\right) - \left(z_2 - z_1\right) \left(-y_2\right) \right\} \\
- \left(y - y_1\right) \left\{ \left(x_2 - x_1\right) \left(-z_2\right) - \left(z_2 - z_1\right) \left(-x_2\right) \right\} \\
+ \left(z - z_1\right) \left\{ \left(x_2 - x_1\right) \left(-y_2\right) - \left(y_2 - y_1\right) \left(-x_2\right) \right\} = 0 \quad (37)
\]

Expanding and simplifying equation (37) gives

\[
x \left(y_1 z_2 - y_2 z_1\right) - y \left(x_1 z_2 - x_2 z_1\right) + z \left(x_1 y_2 - x_2 y_1\right) = 0 \quad (38)
\]

or

\[
Ax - By + Cz = 0 \quad (39)
\]

where \( A, B \) and \( C \) are functions of the coordinates of the terminal points \( P_1 \) and \( P_2 \)

\[
A = y_1 z_2 - y_2 z_1 \quad B = x_1 z_2 - x_2 z_1 \quad C = x_1 y_2 - x_2 y_1 \quad (40)
\]

Replacing \( x, y \) and \( z \) with their equivalents, given by equations (32), gives

\[
\nu \cos \phi \cos \lambda \left(y_1 z_2 - y_2 z_1\right) - \nu \cos \phi \sin \lambda \left(x_1 z_2 - x_2 z_1\right) + \nu \left(1 - e^2\right) \sin \phi \left(x_1 y_2 - x_2 y_1\right) = 0
\]

and dividing both sides by \( \nu \cos \phi \) gives the equation of the great elliptic as

\[
A \cos \lambda - B \sin \lambda + C \left(1 - e^2\right) \tan \phi = 0 \quad (41)
\]

Equation (41) is not suitable for computing the distance along a great elliptic arc, nor is it suitable for computing the azimuth of the curve, but by certain re-arrangements it is possible to solve (directly) for the latitude of a point on the curve given a longitude somewhere between the longitudes of the terminal points of the curve. Or alternatively, solve (iteratively) for the longitude of a point given a latitude somewhere between the latitudes of the terminal points.
Solving for the latitude

A simple re-arrangement of equation (41) allows the latitude $\phi$ to be evaluated from

$$\tan \phi = \frac{B \sin \lambda - A \cos \lambda}{C \left(1 - e^2\right)}$$  \hspace{1cm} (42)

where $A$ and $B$ and $C$ are functions of terminal points $P_1$ and $P_2$ given by equations (40).

Solving for the longitude

The longitude $\lambda$ can be evaluated using Newton-Raphson iteration for the real roots of the equation $f(\lambda) = 0$ given in the form of an iterative equation

$$\lambda_{(n+1)} = \lambda_{(n)} - \frac{f\left(\lambda_{(n)}\right)}{f'\left(\lambda_{(n)}\right)}$$  \hspace{1cm} (43)

where $n$ denotes the $n^{th}$ iteration and $f(\lambda)$ is given by equation (41) as

$$f(\lambda) = A \cos \lambda - B \sin \lambda + C \left(1 - e^2\right) \tan \phi$$  \hspace{1cm} (44)

and the derivative $f'(\lambda) = \frac{df}{d\lambda} \left\{ f(\lambda) \right\}$ is given by

$$f'(\lambda) = -A \sin \lambda - B \cos \lambda$$  \hspace{1cm} (45)

An initial value of $\lambda_{(1)}$ ($\lambda$ for $n = 1$) can be taken as the longitude of $P_1$ and the functions $f\left(\lambda_{(1)}\right)$ and $f'\left(\lambda_{(1)}\right)$ evaluated from equations (44) and (45) using $\lambda_1$. $\lambda_{(2)}$ ($\lambda$ for $n = 2$) can now be computed from equation (43) and this process repeated to obtain values $\lambda_{(2)}, \lambda_{(4)}, \ldots$. This iterative process can be concluded when the difference between $\lambda_{(n+1)}$ and $\lambda_{(n)}$ reaches an acceptably small value.

Alternatively, the longitude can be evaluated by a trigonometric equation derived as follows. Equation (41) can be expressed as

$$B \sin \lambda - A \cos \lambda = C \left(1 - e^2\right) \tan \phi$$  \hspace{1cm} (46)

and $A$, $B$ and $C$ are given by equations (40). Equation (46) can be expressed as a trigonometric addition of the form

$$C \left(1 - e^2\right) \tan \phi = q \cos (\lambda - \delta)$$

$$= q \cos \lambda \cos \delta + q \sin \lambda \sin \delta$$  \hspace{1cm} (47)

Now, equating the coefficients of $\cos \lambda$ and $\sin \lambda$ in equations (47) and (46) gives
\[ A = -q \cos \delta; \quad B = q \sin \delta \] (48)

and using these relationships

\[ q = \sqrt{A^2 + B^2}; \quad \tan \delta = \frac{B}{A} \] (49)

Substituting these results into equation (47) gives

\[
\lambda = \arccos \left[ \frac{C \left(1 - e^2\right) \tan \phi}{\sqrt{A^2 + B^2}} \right] + \arctan \left[ \frac{B}{-A} \right]
\] (50)

THE VERTEX OF THE GREAT ELLIPTIC

As \( P \) moves along a great elliptic its latitude and longitude is varying (unless the great elliptic is the equator or a meridian, in which case either latitude or longitude will be constant) and differentiating equation (41) with respect to latitude \( \phi \) and re-arranging gives the derivative

\[
\frac{d\phi}{d\lambda} = \frac{A \sin \lambda + B \cos \lambda}{C \left(1 - e^2\right) \sec^2 \phi}
\] (51)

Now when \( \frac{d\phi}{d\lambda} = 0 \) the latitude will be a maximum and \( P \) will have reached a vertex \( \phi_v, \lambda_v \) and (51) becomes \( \frac{d\phi}{d\lambda} = 0 = A \sin \lambda_v + B \cos \lambda_v \) from which we obtain

\[
\lambda_v = \arctan \left[ \frac{B}{-A} \right]
\] (52)

And substituting (52) into (41) and re-arranging gives

\[
\phi_v = \arctan \left[ \frac{B \sin \lambda_v - A \cos \lambda_v}{C \left(1 - e^2\right)} \right]
\] (53)

Using (29) gives the geocentric latitude of the vertex as

\[
\theta_v = \arctan \left[ \frac{B \sin \lambda_v - A \cos \lambda_v}{C} \right]
\] (54)
GEOMETRIC PARAMETERS OF THE GREAT ELLIPTIC

The semi-major axis of the great elliptic is $a$, the radius of the equator and the semi-major axis of the ellipsoid. The semi-minor axis of the great elliptic is the distance $OV = b'$ (see Figure 1) and an expression for $b'$ is obtained from (31) [the polar equation for an ellipse]

$$b' = \frac{a}{\sqrt{1 + e'^2 \sin^2 \theta}} = \frac{b}{\sqrt{1 - e^2 \cos^2 \theta}}$$  \hspace{1cm} (55)

Denoting $\varepsilon$ and $\varepsilon'$ as the first and second eccentricities of the great elliptic (having semi-axes $a,b'$ and $a > b'$) $\varepsilon$ and $\varepsilon'$ are defined by

$$\varepsilon^2 = \frac{a^2 - b'^2}{a^2}$$  \hspace{1cm} (56)

$$\varepsilon'^2 = \frac{a^2 - b'^2}{b'^2}$$  \hspace{1cm} (57)

And using (55) and (56) the second eccentricity of the great elliptic is

$$\varepsilon'^2 = \varepsilon'^2 \sin^2 \theta$$  \hspace{1cm} (58)

THE AZIMUTH $\alpha$ OF THE GREAT ELLIPTIC

The azimuth $\alpha$ of a great elliptic at $P$ ($\alpha_1$ at $P_1$ in Figure 1) is the clockwise angle between the tangent to the ellipsoid meridian and the tangent to the great elliptic. Both tangents lie in the tangent plane to the ellipsoid at $P$. The forward azimuth of the great elliptic from $P_1$ to $P_2$ is denoted $\alpha_{12}$ and $\alpha_{12} = \alpha_1$ (see Figure 1). The reverse azimuth ($P_2$ to $P_1$) is denoted $\alpha_{21}$ and $\alpha_{21} = \alpha_2 + 180^\circ$.

The azimuth can be obtained by a series of vector manipulations (scalar and vector products; see Appendix 1) that are outlined below.

The position vector of $P$ on the surface of the ellipsoid is (Deakin & Hunter 2010a)

$$\mathbf{r} = \mathbf{r}(\phi, \lambda) = \frac{c}{V} \cos \phi \cos \lambda \mathbf{i} + \frac{c}{V} \cos \phi \sin \lambda \mathbf{j} + \frac{b}{V} \sin \phi \mathbf{k}$$  \hspace{1cm} (59)

and the partial derivatives of the position vector are

$$\mathbf{r}_\phi = \frac{\partial}{\partial \phi} \mathbf{r}(\phi, \lambda) = -\frac{c}{V^3} \sin \phi \cos \lambda \mathbf{i} - \frac{c}{V^3} \sin \phi \sin \lambda \mathbf{j} + \frac{c}{V^3} \cos \phi \mathbf{k}$$  \hspace{1cm} (60)

$$\mathbf{r}_\lambda = \frac{\partial}{\partial \lambda} \mathbf{r}(\phi, \lambda) = -\frac{c}{V} \cos \phi \sin \lambda \mathbf{i} + \frac{c}{V} \cos \phi \cos \lambda \mathbf{j} + 0 \mathbf{k}$$  \hspace{1cm} (61)
where \( \mathbf{r}_\phi \) and \( \mathbf{r}_\lambda \) are orthogonal and tangential to the parametric curves \( \lambda = \text{constant} \) (meridian) and \( \phi = \text{constant} \) (parallel). \( \mathbf{r}_\phi \) points north and \( \mathbf{r}_\lambda \) points east and both vectors lie in the tangent plane to the ellipsoid at \( P \).

Now, denote two unit vectors pointing north and east respectively as \( \mathbf{\hat{n}} = \frac{\mathbf{r}_\phi}{|\mathbf{r}_\phi|} \) and \( \mathbf{\hat{e}} = \frac{\mathbf{r}_\lambda}{|\mathbf{r}_\lambda|} \) and

\[
\mathbf{\hat{n}} = -\sin \phi \cos \lambda \mathbf{i} - \sin \phi \sin \lambda \mathbf{j} + \cos \phi \mathbf{k} \tag{62}
\]
\[
\mathbf{\hat{e}} = -\sin \lambda \mathbf{i} + \cos \lambda \mathbf{j} + 0 \mathbf{k} \tag{63}
\]

The unit vector normal to the surface (pointing inwards) is denoted \( \mathbf{\hat{N}} \) and found from the vector cross product as

\[
\mathbf{\hat{N}} = \mathbf{\hat{n}} \times \mathbf{\hat{e}} = -\cos \phi \cos \lambda \mathbf{i} - \cos \phi \sin \lambda \mathbf{j} - \sin \phi \mathbf{k} \tag{64}
\]

\( \mathbf{\hat{n}} \), \( \mathbf{\hat{e}} \) and \( \mathbf{\hat{N}} \) form a triplet of orthogonal unit vectors.

Now, the great elliptic plane is given by (39) as \( Ax - By + Cz = 0 \) and the unit vector normal to this plane (directed outwards from the origin) is denoted by \( \mathbf{\hat{p}} \) and

\[
\mathbf{\hat{p}} = l \mathbf{i} + m \mathbf{j} + n \mathbf{k} \tag{65}
\]

where \( l \), \( m \) and \( n \) are direction cosines \( (l^2 + m^2 + n^2 = 1) \) given by

\[
l = \frac{A}{\sqrt{A^2 + B^2 + C^2}}; \quad m = \frac{-B}{\sqrt{A^2 + B^2 + C^2}}; \quad n = \frac{C}{\sqrt{A^2 + B^2 + C^2}} \tag{66}
\]

and \( A \), \( B \) and \( C \) are constants of the great elliptic given by (40).

Now the vector cross product of the two unit vectors \( \mathbf{\hat{N}} \) and \( \mathbf{\hat{p}} \) at \( P_1 \) will produce a vector perpendicular to both and in the direction to \( P_2 \). This vector denoted \( \mathbf{g} \) (and its unit vector \( \mathbf{\hat{g}} \)) will lie in the tangent plane at \( P_1 \) and

\[
\mathbf{g} = \mathbf{\hat{N}} \times \mathbf{\hat{p}} \quad \text{and} \quad \mathbf{\hat{g}} = \frac{g}{|\mathbf{g}|} \tag{67}
\]

The vector dot product can now be used to compute angles \( \alpha \) and \( \beta \) in the tangent plane; where \( \alpha \) is the angle between the unit vectors \( \mathbf{\hat{n}} \) (pointing north) and \( \mathbf{\hat{g}} \)

\[
\alpha = \arccos \left\{ \mathbf{\hat{n}} \cdot \mathbf{\hat{g}} \right\} \tag{68}
\]

and \( \beta \) is the angle between the unit vector \( \mathbf{\hat{e}} \) (pointing east) and \( \mathbf{\hat{g}} \).
\[ \beta = \arccos \{ \mathbf{e} \cdot \mathbf{g} \} \]  

The azimuth \( \alpha_1 = \alpha_{12} \) of the great elliptic from \( P_1 \) to \( P_2 \) is then determined from the rule:

\[
\text{IF } \beta > 90^\circ \text{ THEN } \alpha_{12} = 360^\circ - \alpha \text{ ELSE } \alpha_{12} = \alpha
\]  

THE AZIMUTH \( \alpha \) OF THE GREAT ELLIPTIC – THOMAS’ APPROACH

The American mathematician Paul D. Thomas (Thomas 1965) developed a trigonometric formula for azimuth, based on vector manipulations, which is outlined here. Consider a rotated Cartesian frame \( x', y', z' \) where the \( x'-y' \) plane is the plane of the equator, the \( z' \)-axis is coincident with \( z \)-axis and the \( z'-x' \) plane is the meridian plane of \( P_1 \). The Cartesian coordinates of \( P_1 \) and \( P_2 \) in this rotated system are:

\[
x_1' = \frac{c}{V_1} \cos \phi_1 \quad x_2' = \frac{c}{V_2} \cos \phi_2 \cos \Delta \lambda \\
y_1' = 0 \quad \text{and} \quad y_2' = \frac{c}{V_2} \cos \phi_2 \sin \Delta \lambda \\
z_1' = \frac{b}{V_1} \sin \phi_1 \quad z_2' = \frac{b}{V_2} \sin \phi_2
\]  

where \( \Delta \lambda = \lambda_2 - \lambda_1 \), \( c \) is the polar radius and \( V \) is a latitude function (see equations (5), (6) and (7)). Substituting these expressions into equation (38) and simplifying gives the great elliptic plane as:

\[
A' x' - B' y' + C' z' = 0
\]  

where

\[
A' = -\left(1 - e^2\right) \tan \phi_1 \sin \Delta \lambda \quad B' = \left(1 - e^2\right) \left(\tan \phi_2 - \tan \phi_1 \cos \Delta \lambda\right) \quad C' = \sin \Delta \lambda
\]  

The unit vector perpendicular to the great elliptic plane (pointing outwards from the origin) is \( \mathbf{p}' = \frac{A'}{d} \mathbf{i} + \frac{-B'}{d} \mathbf{j} + \frac{C'}{d} \mathbf{k} \) where \( d = \sqrt{A'^2 + B'^2 + C'^2} \) and the unit vector normal to the tangent plane at \( P_1 \) (pointing inwards) is \( \mathbf{N}' = -\cos \phi_1 \mathbf{i} - 0 \mathbf{j} - \sin \phi_1 \mathbf{k} \). The tangent to the meridian at \( P_1 \) (pointing north) is \( \mathbf{n}' = -\sin \phi_1 \mathbf{i} - 0 \mathbf{j} + \cos \phi_1 \mathbf{k} \) and similarly to before, the vector tangential to the great elliptic and in the tangent plane at \( P_1 \) is \( \mathbf{g}' = \mathbf{N}' \times \mathbf{p}' = -\frac{B'}{d} \sin \phi_1 \mathbf{i} + \left[\frac{C'}{d} \cos \phi_1 + \frac{A'}{d} \sin \phi_1\right] \mathbf{j} + \frac{B'}{d} \cos \phi_1 \mathbf{k} \) having magnitude \( |\mathbf{g}'| = \frac{1}{d} \sqrt{B'^2 + \left(C' \cos \phi_1 - A' \sin \phi_1\right)^2} \) and unit vector \( \mathbf{g}' = \frac{\mathbf{g}'}{|\mathbf{g}'|} \).
Using unit vectors, \( \cos \alpha_1 = \frac{B'}{\sqrt{B'^2 + (C' \cos \phi - A' \sin \phi)^2}} \) which after some algebra reduces to

\[
\sin^2 x + \cos^2 x = 1 \quad \text{we obtain} \quad \sin \alpha_1 = \frac{C' \cos \phi - A' \sin \phi}{\sqrt{B'^2 + (C' \cos \phi - A' \sin \phi)^2}}; \quad \text{and then}
\]

\[
\tan \alpha_1 = \frac{C' \cos \phi - A' \sin \phi}{B'} \cdot \text{Substituting expressions for } A', B', C' \text{ given by (73) and simplifying gives}
\]

\[
\alpha_1 = \arctan \left( \frac{a^2 \sin \Delta \lambda}{\nu_1^2 \left( 1 - e^2 \right) \left( \tan \phi_2 - \tan \phi_1 \cos \Delta \lambda \cos \phi \right)} \right) \quad (74)
\]

Evaluating \( \alpha_1 \) in the range \(-180^\circ \leq \alpha_1 \leq 180^\circ \) gives the azimuth \( \alpha_{12} \) from the rule:

\[
\text{IF } \alpha_1 < 0 \text{ THEN } \alpha_{12} = 360^\circ + \alpha_1 \text{ ELSE } \alpha_{12} = \alpha_1 \quad (75)
\]

Following Thomas (1965); by symmetrical interchange of subscripts and replacing \( \Delta \lambda \) by \(-\Delta \lambda\) the azimuth from \( P_2 \) to \( P_1 \) is

\[
\alpha_2 = \arctan \left( \frac{a^2 \sin \Delta \lambda}{\nu_2^2 \left( 1 - e^2 \right) \left( \tan \phi_2 \cos \Delta \lambda - \tan \phi_1 \cos \phi_2 \right)} \right) \quad (76)
\]

Evaluating \( \alpha_2 \) in the range \(-180^\circ \leq \alpha_2 \leq 180^\circ \) gives the azimuth \( \alpha_{21} \) from the rule:

\[
\text{IF } \alpha_2 < 0 \text{ THEN } \alpha_{21} = 540^\circ + \alpha_2 \text{ ELSE } \alpha_{21} = \alpha_2 + 180^\circ \quad (77)
\]

[Note that Thomas’ equations for azimuth (Thomas 1965, p. 47, equations (15),(16)) are different from (74) and (76) as Thomas defines azimuth as a clockwise angle measured from south, see p. 45, equation (9)]

**GREAT ELLIPTIC LATITUDES**

A point \( P \) on the great elliptic has ‘great elliptic’ latitudes \( \phi' \) and \( \theta' \) that are analogous to (geodetic) latitude \( \phi \) and geocentric latitude \( \theta \) noting that the great elliptic arc \( EPV \) of Figure 1 is similar to the meridian arc \( FPN \). In fact we could consider the vertex \( V \) of the great elliptic as analogous to the pole \( N \) of a meridian. Expressions for \( \phi' \) and \( \theta' \) are developed below.
In Figure 1, consider two vectors \( \mathbf{E} = \overrightarrow{OE} = x_E \mathbf{i} + y_E \mathbf{j} + z_E \mathbf{k} \) and \( \mathbf{P} = \overrightarrow{OP} = x \mathbf{i} + y \mathbf{j} + z \mathbf{k} \) where \( \mathbf{i}, \mathbf{j}, \mathbf{k} \) are unit vectors in the direction of the Cartesian axes and \( x_E, y_E, z_E \) and \( x, y, z \) are Cartesian coordinates of \( E \) and \( P \) respectively. The vector dot product is

\[
\mathbf{E} \cdot \mathbf{P} = \| \mathbf{E} \| \| \mathbf{P} \| \cos \theta' = x_E x + y_E y + z_E z
\]

and a re-arrangement of (78) gives an expression for great elliptic geocentric latitude \( \theta' \) as

\[
\cos \theta' = \frac{x_E x + y_E y + z_E z}{\| \mathbf{E} \| \| \mathbf{P} \|}
\]

where the Cartesian coordinates are obtained from (32) as

\[
\begin{align*}
    x_E &= a \cos \lambda_E & x &= \nu \cos \phi \cos \lambda \\
    y_E &= a \sin \lambda_E & y &= \nu \cos \phi \sin \lambda \\
    z_E &= 0 & z &= \nu (1 - e^2) \sin \phi \\
\end{align*}
\]

\( \| \mathbf{E} \| = \sqrt{x_E^2 + y_E^2 + z_E^2} \) and \( \| \mathbf{P} \| = \sqrt{x^2 + y^2 + z^2} \) are the magnitudes of vectors \( \mathbf{E} \) and \( \mathbf{P} \).

Now \( \| \mathbf{E} \| \) is just the semi-major axis \( a \); and \( \| \mathbf{P} \| = \frac{a}{W} \sqrt{W^2 (2 - e^2) - (1 - e^2)} \) is obtained after some algebra noting that \( W \) is a latitude function defined by (7). Substituting these results and (80) into (79) and simplifying gives

\[
\theta' = \arccos \left( \frac{\cos \phi \cos \left( \lambda - \lambda_E \right)}{\sqrt{W^2 (2 - e^2) - (1 - e^2)}} \right)
\]

And using the relationships between latitudes given in (29) we have

\[
\phi' = \arctan \left( \frac{\tan \theta'}{1 - e^2} \right)
\]

THE AUXILIARY SPHERE AND THE GREAT ELLIPTIC

Following Bowring (1984) several formula, useful in the solution of the direct and inverse problems, can be developed using spherical trigonometry and an auxiliary sphere. This auxiliary sphere has a radius \( r_1 = OP \) \((b \leq r_1 \leq a)\) and is centred at \( O \) the centre of the ellipsoid.
Figure 3a:  
Great elliptic through $P_1$ and $P_2$ 

Figure 3b:  
Great circle through $P_1$ and $P'_2$ 

Figure 3a shows the great elliptic arc $s = P_1P_2$ on the ellipsoid having (forward) azimuth $\alpha_{12} = \alpha_1$ and reverse azimuth $\alpha_{21} = \alpha_2 + 180^\circ$; and azimuth $\alpha = 90^\circ$ at the vertex $V$. Figure 3b shows the great elliptic plane $OP_1P_2$ intersecting the auxiliary sphere along the great circle arc $P_1V'P'_2$. The great circle arc of length $\sigma = P_1P'_2$ has spherical azimuth $A_1$ at $P_1$, $A_2$ at $P'_2$ and $A = 90^\circ$ at the vertex $V'$. And points $P_1$, $V'$ and $P'_2$ have spherical latitudes equal to the geocentric latitudes of $P_1$, $V$ and $P_2$ on the ellipsoid.

In the spherical triangle $P_1N'P'_2$ in Figure 3b with $\Delta \lambda = \lambda_2 - \lambda_1$ the cotangent formula (four-parts rule) of spherical trigonometry may be used to give expressions for spherical azimuth $A_1$ (Bowring 1984) and longitude difference $\Delta \lambda$

$$A_1 = \arctan \left[ \frac{\sin \Delta \lambda}{\cos \theta_1 \tan \theta_2 - \sin \theta_1 \cos \Delta \lambda} \right]$$

(83)

$$\Delta \lambda = \arctan \left[ \frac{\sin A_1}{\cos \frac{\theta_1}{\tan \sigma - \sin \theta_1 \cos A_1}} \right]$$

(84)

In the same spherical triangle, the cosine formula for spherical trigonometry gives expressions for geocentric latitude $\theta_2$ and spherical arc length $\sigma$

$$\theta_2 = \arcsin \left( \sin \theta_1 \cos \sigma + \cos \theta_1 \sin \sigma \cos A_1 \right)$$

(85)

$$\sigma = \arccos \left( \sin \theta_1 \sin \theta_2 + \cos \theta_1 \cos \theta_2 \cos \Delta \lambda \right)$$

(86)
When distances are small the spherical angles $\sigma$ and $\Delta \lambda$ will be small and equation (86) may give unreliable results. Two better formulas for evaluating $\sigma$ are:

$$
\sigma = \arcsin \sqrt{\left( \cos \theta_1 \sin \theta_2 - \sin \theta_1 \cos \theta_2 \cos \Delta \lambda \right)^2 + \left( \cos \theta_2 \sin \Delta \lambda \right)^2}
$$

(87)

and

$$
\sigma = 2 \arctan \sqrt{\frac{x}{1-x}}
$$

(88)

where $x = \sin^2 \frac{1}{2} \Delta \theta + \cos \theta_1 \cos \theta_2 \sin^2 \frac{1}{2} \Delta \lambda$, $\Delta \theta = \theta_2 - \theta_1$ and $\Delta \lambda = \lambda_2 - \lambda_1$.

Equation (87) can be obtained from the five-parts cosine formula for spherical trigonometry and is used by Vincenty (1975, eq. 14, p. 90) in the equations for solving the inverse problem of the geodesic on the ellipsoid. Equation (88) is the ‘haversine’ formula (Sinnott 1984) where versine (versed sine) and haversine (half versine) are trigonometric functions defined as versine $\beta = 1 - \cos \beta$ and haversine $\beta = \frac{1}{2} (1 - \cos \beta) = \sin^2 \frac{1}{2} \beta$.

In the right-angled spherical triangle $P_1N'V'$ in Figure 3b we may use Napier’s rules of circular parts to give expressions for geocentric latitude and the longitude of the vertex

$$
\theta_v = \arccos \left( \frac{\sin A}{\cos \theta_1} \right)
$$

(89)

$$
\lambda_v = \arctan \left( \frac{1}{\sin \theta_1 \tan A} \right) + \lambda_1
$$

(90)

Bowring (1984) gives an expression for $\sin^2 \theta_v$ that can be obtained from (89) using the trigonometric identity $\sin^2 x + \cos^2 x = 1$ to give

$$
\sin^2 \theta_v = \sin^2 \theta_1 + \cos^2 \theta_1 \cos^2 A
$$

(91)

Equation (91) can be used in (55) to compute the semi-major axis of the great elliptic.

**RELATIONSHIP BETWEEN AZIMUTH $\alpha_1$ AND SPHERICAL AZIMUTH $A_1$**

The azimuth $\alpha$ of a great elliptic at $P$ ($\alpha_1$ at $P_1$ and $\alpha_2$ at $P_2$ in Figure 3a) is the clockwise angle between the tangent to the ellipsoid meridian and the tangent to the great elliptic. Both these tangents lie in the tangent plane to the ellipsoid at $P$. The spherical azimuth $A$ ($A_1$ at $P_1$ and $A_2$ at $P_2'$ in Figure 3b) is an angle in a spherical triangle and is equal to the angle between the tangents to the intersecting great circle planes. These tangents lie in the tangent plane to the auxiliary sphere. At $P_1$, where the radius of the auxiliary sphere is $r_1 = OP_1$ the two tangent planes will intersect (the line of intersection is
perpendicular to the meridian plane at \( P_1 \) and a relationship can be established between \( \alpha_1 \) and \( A_1 \) by considering Figure 4

![Diagram](https://via.placeholder.com/150)

**Figure 4: Tangent planes at \( P_1 \) on the ellipsoid**

Figure 4 shows two tangent planes at \( P_1 \): (i) the plane \( P_1QRS \) that is tangential to the auxiliary sphere, and (ii) the plane \( P_1Q'R'S' \) tangential to the ellipsoid. The plane \( P_1RR' \) is coincident with the great elliptic plane and the great circle plane that both contain the centre of the ellipsoid \( O \) and the point \( P_2 \). \( P_1R \) and \( P_1R' \) are tangential to the great circle and the great elliptic respectively. The plane \( P_1QQ' \) is coincident with the meridian planes of the auxiliary sphere and the ellipsoid. And both planes contain the centre of the ellipsoid \( O \), the point \( H \) on the minor axis and both poles \( N \) and \( N' \) (see Figures 2 and 3). The directions from \( P_1 \) to \( H \) and \( P_1 \) to \( O \) are the directions of the normal to the ellipsoid and the normal to the auxiliary sphere respectively and their difference \( \phi_1 - \theta_1 \) is the angle \( QP_1Q' \). The spherical azimuth \( A_1 \) is the angle \( QP_1R \) and the azimuth \( \alpha_1 \) is the angle \( Q'R_1P' \).

In triangle \( P_1QR \) we have \( \tan A_1 = \frac{QR}{P_1Q} \) and in triangle \( P_1Q'R' \) we have \( \tan \alpha_1 = \frac{Q'R'}{P_1Q'} \).

But, \( QR = Q'R' \) and \( P_1Q = P_1Q' \cos (\phi_1 - \theta_1) \), hence \( \tan A_1 = \frac{Q'R'}{P_1Q' \cos (\phi_1 - \theta_1)} \) and

\[
\tan \alpha_1 = \tan A_1 \cos (\phi_1 - \theta_1) \tag{92}
\]

Hence

\[
\alpha_1 = \arctan \left\{ \tan A_1 \cos (\phi_1 - \theta_1) \right\} \tag{93}
\]
\[ A_i = \arctan \left( \frac{\tan \alpha_i}{\cos \left( \phi_i - \theta_i \right)} \right) \]  

(94)

THE DIRECT PROBLEM ON THE ELLIPSOID USING A GREAT ELLIPTIC

The direct problem is: Given latitude and longitude of \( P_1 \), azimuth \( \alpha_{12} \) of the great elliptic section \( P_1P_2 \) and the arc length \( s \) along the great elliptic curve; compute the latitude and longitude of \( P_2 \).

With the ellipsoid constants \( a, f, e^2 \) and \( e'^2 \) and given \( \phi_1, \lambda_1, \alpha_{12} \) and \( s \) the problem may be solved by the following sequence.

1. Compute the geocentric latitude \( \theta'_1 \) at \( P_1 \) using equation (29) expressed as

\[ \theta'_1 = \arctan \left( \frac{1 - e^2}{(1 - e^2) \tan \phi_1} \right) \]

2. Compute the spherical azimuth \( A_1 \) at \( P_1 \) using equation (94).

3. Compute the geocentric latitude \( \theta_v \) and longitude \( \lambda_v \) of the vertex \( V \) and the latitude \( \phi_v \) of the vertex and the longitude \( \lambda_E \) of the node \( E \) of the great elliptic (see Figures 1 and 3) using equations (89), (29) and (90)

4. Compute the geometric parameters of the great elliptic using equations (55) and equations (1) to (4) given here again as

\[ b' = \frac{a}{\sqrt{1 + e'^2 \sin^2 \theta_v}}; \quad f' = \frac{a - b'}{a}; \quad n' = \frac{f'}{2 - f'}; \quad \varepsilon'^2 = f' \left( 2 - f' \right); \quad \varepsilon'^2 = \frac{e'^2}{1 - e'^2} \]

5. Compute \( x, y, z \) Cartesian coordinates of \( P_1 \) using equations (6), (7) and (32) combined as

\[ x_i = \frac{c}{V_i} \cos \phi_i \cos \lambda_i; \quad y_i = \frac{c}{V_i} \cos \phi_i \sin \lambda_i; \quad z_i = \frac{b}{V_i} \sin \phi_i \]

6. Compute elliptic geocentric latitude \( \theta'_1 \) and elliptic latitude \( \phi'_1 \) of \( P_1 \) using equations (81) and (82)

7. Compute the meridian distance \( M_1 = EP_1 \) and the quadrant distance \( Q = EV \) of the great elliptic using the series (13) with \( \phi' \) and \( n' \) replacing \( \phi \) and \( n \). Then compute meridian distance \( M_2 = 2Q - (M_1 \pm s) \) or \( M_2 = M_1 \pm s \) depending on whether \( P_1 \)
8. Compute elliptic latitude $\phi'_2$ of $P_2$ using series (27) with $\phi'$ and $n'$ replacing $\phi$ and $n$ and then the elliptic geocentric latitude $\theta'_2$ from equation (29) expressed as

$$
\theta'_2 = \arctan\left\{(1 - e^2) \tan \phi'_2\right\}
$$

9. Compute the great circle distance $\sigma = P_1P_2 = \left(90^\circ - \theta'_1\right) + \left(90^\circ - \theta'_2\right)$ on the auxiliary sphere.

10. Compute geocentric latitude $\theta_2$ of $P_2$ from spherical trigonometry using equation (85) and then latitude $\phi_2$ from equation (29) expressed as

$$
\phi_2 = \arctan\left\{\frac{\tan \theta_2}{1 - e^2}\right\}
$$

11. Compute longitude difference $\Delta \lambda = \lambda_2 - \lambda_1$ from spherical trigonometry using equation (84) and then longitude of $P_2$

12. Compute reverse azimuth $\alpha_{21}$ using equation (76).

Shown below is the output of a MATLAB function $GEA\_direct.m$ that solves the direct problem on the ellipsoid for great elliptic sections.

The ellipsoid is the WGS84 ellipsoid and $\phi, \lambda$ for $P_1$ are $35^\circ 45' 55''$ and $140^\circ 23' 08''$ respectively with $\alpha_{12} = 54^\circ 57' 06.932985''$ and $s = 8246278.910557$ m. $\phi, \lambda$ computed for $P_2$ are $37^\circ 37' 08''$ and $-122^\circ 22' 30''$ respectively.

THE INVERSE PROBLEM ON THE ELLIPSOID USING A GREAT ELLIPTIC SECTION

The inverse problem is: Given latitudes and longitudes of \( P_1 \) and \( P_2 \) on the ellipsoid compute the azimuth \( \alpha_{12} \) of the great elliptic section \( P_1P_2 \) and the arc length \( s \) of the great elliptic curve.

With the ellipsoid constants \( a, f, e^2 \) and \( e'^2 \) and given \( \phi_1, \lambda_1 \) and \( \phi_2, \lambda_2 \) the problem may be solved by the following sequence.

1. Compute Cartesian coordinates of \( P_1 \) and \( P_2 \) using equations (32).
2. Compute forward and reverse azimuths using equations (74) and (76)
3. Compute great elliptic constants \( A, B \) and \( C \) using equations (40)
4. Compute latitude and longitude of vertex using equations (52) and (53); and then the geocentric latitude of the vertex using (54)
5. Compute the geometric parameters of the great elliptic (see step 4 in the direct case)
6. Compute elliptic geocentric latitudes $\theta_1', \theta_2'$ and elliptic latitudes $\phi_1', \phi_2'$ of $P_1$ and $P_2$ using equations (81) and (82).

7. Compute great elliptic meridian distances $M_1 = EP_1$ and $M_2 = EP_2$ (or $M_2 = E'P_2$ depending on whether $P_2$ is on the other side of the vertex as in Figure 1) and the quadrant distance $Q$ using the series (13).

8. Compute the great elliptic arc length from $s = |M_2 - M_1|$ or $s = 2Q - (M_1 + M_2)$.

Shown below is the output of a MATLAB function `GEA_inverse.m` that solves the inverse problem on the ellipsoid for great elliptic sections.

The ellipsoid is the WGS84 ellipsoid and $\phi, \lambda$ for $P_1$ are $+35^\circ 45'55''$ and $+140^\circ 23'08''$ respectively and $\phi, \lambda$ for $P_2$ are $+37^\circ 37'08''$ and $-122^\circ 22'30''$ respectively.

Computed azimuths are $\alpha_{12} = 54^\circ 57'06.932985''$ and $\alpha_{21} = 303^\circ 01'14.140673''$, and $s = 8246278.910557$ m.

Geodesic Tokyo→San Francisco:

\[ \alpha_{21} = 54° 49' 04.5529" \quad s = 8246271.872 \text{ m} \quad \alpha_{21} = 303° 09' 21.9006" \]

Geodesic – great elliptic arc = 7.038 m.

**DIFFERENCE IN LENGTH BETWEEN A GEODESIC AND A GREAT ELLIPTIC ARC LENGTH**

There are five curves of interest in geodesy; the geodesic, the normal section, the great elliptic arc the loxodrome and the curve of alignment.

The geodesic between \( P_1 \) and \( P_2 \) on an ellipsoid is the unique curve on the surface defining the shortest distance; all other curves will be longer in length. The normal section curve \( P_1P_2 \) is a plane curve created by the intersection of the normal section plane containing the normal at \( P_1 \) and also \( P_2 \) with the ellipsoid surface. And as we have shown (Deakin & Hunter 2010b) there is the other normal section curve \( P_2P_1 \). The curve of alignment (Deakin & Hunter 2010b, Thomas 1952) is the locus of all points \( P \) such that the normal section plane at \( P \) also contains the points \( P_1 \) and \( P_2 \). The curve of alignment is very close to a geodesic. The great elliptic arc is the plane curve created by intersecting the plane containing \( P_1, P_2 \) and the centre \( O \) with the surface of the ellipsoid and the loxodrome is the curve on the surface that cuts each meridian between \( P_1 \) and \( P_2 \) at a constant angle.

Approximate equations for the difference in length between the geodesic, the normal section curve and the curve of alignment were developed by Clarke (1880, p. 133) and
Bowring (1972, p. 283) developed an approximate equation for the difference between the geodesic and the great elliptic arc. Following Bowring (1972), let

\[ s = \text{geodesic length} \]
\[ L = \text{normal section length} \]
\[ D = \text{great elliptic length} \]
\[ S = \text{curve of alignment length} \]

then

\[
L - s = \frac{e^4}{90} s \left( \frac{s}{R} \right)^4 \cos^4 \phi_1 \sin^2 \alpha_{12} \cos^2 \alpha_{12} + \cdots \\
D - s = \frac{e^4}{24} \left( \frac{s}{R} \right)^2 \sin^2 \phi_1 \cos^2 \phi_1 \sin^2 \alpha_{12} + \cdots \\
S - s = \frac{e^4}{360} s \left( \frac{s}{R} \right)^4 \cos^4 \phi_1 \sin^2 \alpha_{12} \cos^2 \alpha_{12} + \cdots \\
\]

where \( R \) can be taken as the radius of curvature in the prime vertical at \( P \).

Now for a given value of \( s \), say the geodesic Tokyo to San Francisco on the WGS84 ellipsoid, \( D - s \) will be a maximum if \( \phi_1 = 45^\circ \) and \( \alpha_{12} = 90^\circ \) in which case \( \sin^2 \phi_1 \cos^2 \phi_1 \sin^2 \alpha_{12} = \frac{1}{4} \), thus

\[
(D - s) \leq \frac{e^4}{96} s \left( \frac{s}{R} \right)^4 \\
\]

(96)

For the WGS84 ellipsoid where \( f = \frac{1}{2}98.257223563, e^2 = f \left(2 - f\right) \), and for \( s = 8246271.872 \text{ m} \) \( (8246.272 \text{ km}) \) and \( R = 6385442.306 \text{ m} \), equation (96) gives \( D - s < 10.707 \text{ m} \). And from Table 1 \( D = 8246278.910 \) and \( D - s = 7.038 \text{ m} \) which satisfies inequality (96).
APPENDIX 1: Vectors

Vectors are very useful for describing various physical quantities or relationships such as force, velocity, acceleration, distance between objects, etc., that have both magnitude and direction. Vectors are represented by arrows between points or analytically by symbols such as \( \overrightarrow{OP} \), or boldface characters \( \mathbf{A} \) or \( \mathbf{a} \). The magnitude of a vector is denoted by \( |\overrightarrow{OP}| \), \( |\mathbf{A}| \) or \( |\mathbf{a}| \) but it is also common to use \( A \) or \( a \) to represent the magnitude of vectors \( \mathbf{A} \) or \( \mathbf{a} \).

A scalar, on the other hand, is a quantity having magnitude but no direction, e.g., mass, length, time, temperature and any real number.

Laws of Vector Algebra: If \( \mathbf{A} \), \( \mathbf{B} \) and \( \mathbf{C} \) are vectors and \( m \) and \( n \) are scalars then

1. \( \mathbf{A} + \mathbf{B} = \mathbf{B} + \mathbf{A} \)  
   Commutative law for Addition
2. \( \mathbf{A} + (\mathbf{B} + \mathbf{C}) = (\mathbf{A} + \mathbf{B}) + \mathbf{C} \)  
   Associative law for Addition
3. \( m\mathbf{A} = \mathbf{A}m \)  
   Commutative law for Multiplication
4. \( m(n\mathbf{A}) = (mn)\mathbf{A} \)  
   Associative law for Multiplication
5. \( (m+n)\mathbf{A} = m\mathbf{A} + n\mathbf{A} \)  
   Distributive law
6. \( m(\mathbf{A} + \mathbf{B}) = m\mathbf{A} + m\mathbf{B} \)  
   Distributive law

A unit vector is a vector having unit magnitude (a magnitude of one). Unit vectors are denoted by \( \hat{\mathbf{A}} \) or \( \hat{\mathbf{a}} \) and

\[
\hat{\mathbf{A}} = \frac{\mathbf{A}}{|\mathbf{A}|} = \frac{\mathbf{A}}{A}
\]

Any vector \( \mathbf{A} \) can be represented by a unit vector \( \hat{\mathbf{A}} \) in the direction of \( \mathbf{A} \) multiplied by the magnitude of \( \mathbf{A} \). That is, \( \mathbf{A} = A\hat{\mathbf{A}} \).

In an \( x,y,z \) Cartesian reference frame, the vector

\[
\mathbf{A} = A_1\mathbf{i} + A_2\mathbf{j} + A_3\mathbf{k}
\]

has component vectors \( A_1\mathbf{i} \), \( A_2\mathbf{j} \) and \( A_3\mathbf{k} \) in the \( x \), \( y \) and \( z \) directions respectively, where \( \mathbf{i} \), \( \mathbf{j} \) and \( \mathbf{k} \) are unit vectors in the \( x \), \( y \) and \( z \) directions. \( A_1, A_2 \) and \( A_3 \) are scalar components. The magnitude of \( \mathbf{A} \) is

\[
A = |\mathbf{A}| = \sqrt{A_1^2 + A_2^2 + A_3^2}
\]
The unit vector of \( \mathbf{A} \) is
\[
\hat{\mathbf{A}} = \frac{\mathbf{A}}{\|\mathbf{A}\|} = \frac{A}{A} \mathbf{i} + \frac{A_2}{A} \mathbf{j} + \frac{A_3}{A} \mathbf{k}
\]

The scalar product (or dot product) of two vectors \( \mathbf{A} = A_1 \mathbf{i} + A_2 \mathbf{j} + A_3 \mathbf{k} \) and \( \mathbf{B} = B_1 \mathbf{i} + B_2 \mathbf{j} + B_3 \mathbf{k} \) is defined as the product of the magnitudes of \( \mathbf{A} \) and \( \mathbf{B} \) multiplied by the cosine of the angle between them, or
\[
\mathbf{A} \cdot \mathbf{B} = \|\mathbf{A}\| \|\mathbf{B}\| \cos \theta = AB \cos \theta
\]
and
\[
\mathbf{A} \cdot \mathbf{B} = (A_1 \mathbf{i} + A_2 \mathbf{j} + A_3 \mathbf{k}) \cdot (B_1 \mathbf{i} + B_2 \mathbf{j} + B_3 \mathbf{k}) = A_1 B_1 + A_2 B_2 + A_3 B_3
\]
Note that \( \mathbf{A} \cdot \mathbf{B} \) is a scalar and not a vector.

The following laws are valid for scalar products:

1. \( \mathbf{A} \cdot \mathbf{B} = \mathbf{B} \cdot \mathbf{A} \)  
   (Commutative law)
2. \( \mathbf{A} \cdot (\mathbf{B} + \mathbf{C}) = \mathbf{A} \cdot \mathbf{B} + \mathbf{A} \cdot \mathbf{C} \)  
   (Distributive law)
3. \( m (\mathbf{A} \cdot \mathbf{B}) = (mA) \cdot \mathbf{B} = (\mathbf{A} \cdot \mathbf{B}) m \) \( \text{where } m \text{ is a scalar} \)
4. \( \mathbf{i} \cdot \mathbf{i} = \mathbf{j} \cdot \mathbf{j} = \mathbf{k} \cdot \mathbf{k} = 1; \quad \mathbf{i} \cdot \mathbf{j} = \mathbf{j} \cdot \mathbf{k} = \mathbf{k} \cdot \mathbf{i} = 0 \)
5. \( \mathbf{A} \cdot \mathbf{A} = a_1^2 + a_2^2 + a_3^2 \)
6. If \( \mathbf{A} \cdot \mathbf{B} = 0 \), and \( \mathbf{A} \) and \( \mathbf{B} \) are not null vectors then \( \mathbf{A} \) and \( \mathbf{B} \) are perpendicular.

The vector product (or cross product) of two vectors \( \mathbf{A} = A_1 \mathbf{i} + A_2 \mathbf{j} + A_3 \mathbf{k} \) and \( \mathbf{B} = B_1 \mathbf{i} + B_2 \mathbf{j} + B_3 \mathbf{k} \) is a vector \( \mathbf{P} = \mathbf{A} \times \mathbf{B} \) where \( \mathbf{P} \) is a vector perpendicular to the plane containing \( \mathbf{A} \) and \( \mathbf{B} \). The magnitude of \( \mathbf{P} \) is defined as the product of the magnitudes of \( \mathbf{A} \) and \( \mathbf{B} \) multiplied by the sine of the angle between them. The vector product is often expressed as
\[
\mathbf{A} \times \mathbf{B} = \|\mathbf{A}\| \|\mathbf{B}\| \sin \theta \hat{\mathbf{P}} = AB \sin \theta \hat{\mathbf{P}}
\]
where \( \hat{\mathbf{P}} \) is a perpendicular unit vector and the direction of \( \mathbf{P} \) is given by the right-hand-screw rule, i.e., if \( \mathbf{A} \) and \( \mathbf{B} \) are in the plane of the head of a screw, then a clockwise rotation of \( \mathbf{A} \) to \( \mathbf{B} \) through an angle \( \theta \) would mean that the direction of \( \mathbf{P} \) would be the same as the direction of advance of a right-handed screw turned clockwise. The cross product can be written as the expansion of a determinant as
\[
\mathbf{P} = \mathbf{A} \times \mathbf{B} = \begin{vmatrix} (+) & (-) & (+) \\ \mathbf{i} & \mathbf{j} & \mathbf{k} \end{vmatrix} = (A_2 B_3 - A_3 B_2) \mathbf{i} - (A_1 B_3 - A_3 B_1) \mathbf{j} + (A_1 B_2 - A_2 B_1) \mathbf{k}
\]
Note here that the mnemonics $(+), (-), (\pm)$ are an aid to the evaluation of the determinant. The perpendicular vector $P = P_i + P_j + P_k$ has scalar components $P_1 = (A_2B_3 - A_3B_2)$, $P_2 = -(A_1B_3 - A_3B_1)$ and $P_3 = (A_1B_2 - A_2B_1)$.

The following laws are valid for vector products:

1. $A \times B = -B \times A$  \hspace{1cm} [Commutative law for cross products fails]
2. $A \times (B \times C) = A \times B + A \times C$ \hspace{1cm} Distributive law
3. $m(A \times B) = (mA) \times B = A \times (mB) = (A \times B)m$ \hspace{1.cm} where $m$ is a scalar
4. $i \times i = j \times j = k \times k = 0; \hspace{0.5cm} i \times j = k, \hspace{0.5cm} j \times k = i, \hspace{0.5cm} k \times i = j$

**Triple products**

Scalar and vector multiplication of three vectors $A$, $B$ and $C$ may produce meaningful products of the form $(A \cdot B)C$, $A \cdot (B \times C)$ and $A \times (B \times C)$. The following laws are valid:

1. $(A \cdot B)C = A (B \cdot C)
2. (A \cdot B)C = B (C \times A) = C (A \times B)$ \hspace{1.cm} (scalar triple products)
3. $A \times (B \times C) = (A \times B) \times C
4. A \times (B \times C) = (A \cdot C)B - (A \cdot B)C \hspace{1.cm} (vector triple products)$
5. $(A \cdot (B \times C)) = A \cdot (B \times C) + (A \cdot B) \times C
6. (A \times (B \times C)) = A \times (B \times C) + (A \times B) \times C$

**Differentiation of vectors**

If $A$, $B$ and $C$ are differentiable vector functions of a scalar $u$, and $\varphi$ is a differentiable scalar function of $u$, then

1. $\frac{d}{du}(A + B) = \frac{dA}{du} + \frac{dB}{du}
2. \frac{d}{du}(A \cdot B) = A \cdot \frac{dB}{du} + A \cdot \frac{dA}{du}
3. \frac{d}{du}(A \times B) = A \times \frac{dB}{du} + A \times \frac{dA}{du}
4. \frac{d}{du}(\varphi A) = \varphi \frac{dA}{du} + A \frac{d\varphi}{du}
5. \frac{d}{du}(A \cdot (B \times C)) = A \cdot \left(B \times \frac{dC}{du}\right) + A \cdot \left(\frac{dB}{du} \times C\right) + \frac{dA}{du} \cdot (B \times C)
6. \frac{d}{du}(A \times (B \times C)) = A \times \left(B \times \frac{dC}{du}\right) + A \times \left(\frac{dB}{du} \times C\right) + \frac{dA}{du} \times (B \times C)$
**Appendix 2: Taylor's theorem**

This theorem, due to the English mathematician Brook Taylor (1685–1731) enables a function \( f(x) \) near a point \( x = a \) to be expressed from the values \( f(a) \) and the successive derivatives of \( f(x) \) evaluated at \( x = a \).

Taylor's polynomial may be expressed in the following form

\[
f(x) = f(a) + (x - a)f'(a) + \frac{(x - a)^2}{2!}f''(a) + \frac{(x - a)^3}{3!}f'''(a) + \ldots
\]

\[
+ \frac{(x - a)^{n-1}}{(n-1)!}f^{(n-1)}(a) + R_n
\]

(97)

where \( R_n \) is the remainder after \( n \) terms and \( f'(a), f''(a), \ldots \) etc. are derivatives of the function \( f(x) \) evaluated at \( x = a \).

Taylor's theorem can also be expressed as power series

\[
f(x) = \sum_{k=0}^{\infty} \frac{f^{(k)}(a)}{k!}(x - a)^k
\]

(98)

where \( f^{(k)}(a) \equiv \left[ \frac{d^k}{dx^k} f(x) \right]_{x=a} \)

The Taylor series for the function \( (1 - e^2 \sin^2 \phi)^{-\frac{1}{2}} \) evaluated at \( e = 0 \) is

\[
(1 - e^2 \sin^2 \phi)^{-\frac{1}{2}} = 1 + \frac{3}{2} e^2 \sin^2 \phi + \frac{15}{8} e^4 \sin^4 \phi + \frac{35}{16} e^6 \sin^6 \phi + \ldots
\]

and the coefficients of even powers of \( e \) are binomial coefficients \( \frac{3}{2}, \frac{3 \cdot 5}{2 \cdot 4}, \frac{3 \cdot 5 \cdot 7}{2 \cdot 4 \cdot 6} \), etc.
APPENDIX 3: Reversion of a series

If we have an expression for a variable $z$ as a series of powers or functions of another variable $y$ then we may, by a reversion of the series, find an expression for $y$ as series of functions of $z$. Reversion of a series can be done using Lagrange's theorem, a proof of which can be found in Bromwich (1991).

Suppose that

\[ y = z + x F(y) \quad \text{or} \quad z = y - x F(y) \quad (99) \]

then Lagrange's theorem states that for any $f$

\[
\begin{align*}
  f(y) &= f(z) + \frac{x}{1!} F(z) f'(z) \\
       &\quad + \frac{x^2}{2!} \frac{d}{dz} \left[ F(z)^2 f'(z) \right] \\
       &\quad + \frac{x^3}{3!} \frac{d^3}{dz^3} \left[ F(z)^3 f'(z) \right] \\
       &\quad + \cdots \\
       &\quad + \frac{x^n}{n!} \frac{d^{n-1}}{dz^{n-1}} \left[ F(z)^n f'(z) \right] \\
       &\quad + \cdots
\end{align*}
\]

(100)

As an example, consider the series for rectifying latitude $\mu$

\[ \mu = \phi + d_2 \sin 2\phi + d_4 \sin 4\phi + d_6 \sin 6\phi + \cdots \quad (101) \]

And we wish to find an expression for $\phi$ as a function of $\mu$.

Comparing the variables in equations (101) and (99), $z = \mu$, $y = \phi$ and $x = -1$; and if we choose $f(y) = y$ then $f(z) = z$ and $f'(z) = 1$. So equation (101) can be expressed as

\[ \mu = \phi + F(\phi) \quad (102) \]

and Lagrange's theorem gives

\[
\begin{align*}
  \phi &= \mu - F(\mu) + \frac{d}{d\mu} \left[ \frac{d}{d\mu} \left( F(\mu) \right)^2 \right] - \frac{1}{6} \frac{d^3}{d\mu^3} \left[ F(\mu) \right]^3 + \frac{1}{24} \frac{d^3}{d\mu^3} \left[ F(\mu) \right]^4 - \cdots \\
       &\quad + \frac{(-1)^n}{n!} \frac{d^{n-1}}{d\mu^{n-1}} \left[ F(\mu) \right]^n + \cdots
\end{align*}
\]

(103)

where

\[ F(\phi) = d_2 \sin 2\phi + d_4 \sin 4\phi + d_6 \sin 6\phi + \cdots \]

and so

\[ F(\mu) = d_2 \sin 2\mu + d_4 \sin 4\mu + d_6 \sin 6\mu + \cdots \]
APPENDIX 4: Maxima

We now show the Maxima ‘program’ used in determining the coefficients of equations (13), (23) and (27) saved as a text file Tseng_nSeries_Horner.mac and run in batch mode silently.

/maxima program to develop series equations for:

1. meridian distance M as a function of latitude B
   \[ M = \frac{a}{1+n} \left( c_0 B + c_2 \sin(2B) + c_4 \sin(4B) + c_6 \sin(6B) + \ldots \right) \]

2. rectifying latitude u as a function of latitude B
   \[ u = B + d_2 \sin(2B) + d_4 \sin(4B) + d_6 \sin(6B) + \ldots \]

3. latitude B as a function of rectifying latitude u
   \[ B = u + D_2 \sin(2u) + D_4 \sin(4u) + D_6 \sin(6u) + \ldots \]

The coefficients in each of these equations are functions of powers of the third flattening \( n = \frac{(a-b)}{(a+b)} \) where \( a \) and \( b \) (\( a > b \)) are the semi-axes of the reference ellipsoid.

******************************************************************************
/**-------------------
** Lagrange reversion
**-------------------

Suppose that we have a series expression for conformal latitude \( b \) as a function of latitude \( B \) having the form
\[ b = B + g_2 \sin(2B) + g_4 \sin(4B) + g_6 \sin(6B) + \ldots \quad (1) \]
g2, g4, g6, etc. are coefficients containing powers of \( \varepsilon \).

We wish to reverse the series (1) to obtain latitude \( B \) as a function of conformal latitude \( b \) having the form
\[ B = b + G_2 \sin(2b) + G_4 \sin(4b) + G_6 \sin(6b) + \ldots \quad (2) \]
G2, G4, G6, etc. are coefficients containing powers of \( \varepsilon \).

Write
\[ b = B + F(B) \]
\[ B = b + f(b) \]
\[ F(B) = \sum (g[2*k] \sin(2*k*B)) \], \( k = 1 \) to \( \infty \)
\[ f(b) = \sum (G[2*k] \sin(2*k*b)) \], \( k = 1 \) to \( \infty \)

Lagrange’s inversion theorem gives
\[ f(b) = - F(b) + \frac{1}{2!} \text{diff1}([F(b)]^2) - \frac{1}{3!} \text{diff2}([F(b)]^3) + \frac{1}{4!} \text{diff3}([F(b)]^4) - \ldots \quad (3) \]
or
\[ f(b) = \sum (-1)^n/n! \cdot \text{diff}(F(b)^n,b,n-1), \quad n = 1 \) to \( \infty \)
The following Maxima code for function Lagrange() was sent to me by Charles Karney 03-Jun-2010 and has been slightly modified by changing the function name and certain variable names.

```
reverse
var2 = expr(var1) = series in eps
to
var1 = revertexpr(var2) = series in eps
Require that expr(var1) = var1 to order eps^0. This throws in a
trigreduce to convert to multiple angle trig functions.
*/

Lagrange(expr,var1,var2,eps,pow):=block
  ([b_acc:1,B_acc:0,dB],
   dB:ratdisrep(taylor(expr-var1,eps,0,pow)),
   dB:subst([var1=var2],dB),
   for n:1 thru pow do
     (b_acc:trigreduce(ratdisrep(taylor(-dB*b_acc/n,eps,0,pow))),'
      B_acc:B_acc+expand(diff(b_acc,var2,n-1))'),
   var2+B_acc$)

/*********************************************************

coefficients in Horner form

$\frac{2}{e} \left( \frac{2}{e} \left( \frac{2}{e} \left( \frac{2}{e} \left( 43659 e + 44100 \right) + 44800 \right) + 46080 \right) + 49152 \right) + 65536$

$b_0 = \frac{2}{e} \left( \frac{2}{e} \left( \frac{2}{e} \left( \frac{2}{e} \left( -72765 e - 70560 \right) - 67200 \right) - 61440 \right) - 49152 \right)$

$b = \frac{2}{e} \left( \frac{2}{e} \left( \frac{2}{e} \left( 10395 e + 8820 \right) + 6720 \right) + 3840 \right)$

$b = \frac{2}{e} \left( \frac{2}{e} \left( \frac{2}{e} \left( -31185 e - 20160 \right) - 8960 \right) \right)$

$b = \frac{2}{e} \left( \frac{2}{e} \left( \frac{2}{e} \left( 524288 \right) + 131072 \right) \right)$

$b = \frac{2}{e} \left( \frac{2}{e} \left( \frac{2}{e} \left( 693 e \right) \right) \right)$
equation for RECTIFYING LATITUDE \( u \) as a function of LATITUDE \( B \)
\[
    u = B + g_2 \sin(2B) + g_4 \sin(4B) + g_6 \sin(6B) + \ldots
\]

\[
    g = - \frac{1533}{2} - \frac{141}{32768} - \frac{111}{2048} - \frac{3}{1024} - \frac{3}{16} - \frac{3}{8}
\]

\[
    g = \frac{165}{4} + \frac{405}{4096} + \frac{15}{8192} + \frac{15}{256} + \frac{3}{256}
\]

\[
    g = \frac{262144}{10} + \frac{2048}{8} + \frac{3072}{4}
\]

\[
    g = \frac{315}{2} + \frac{315}{65536} + \frac{693}{131072}
\]

coefficients in Horner form

\[
    \begin{align*}
    g_2 & = e e (e (-1533 e - 2256) - 3552) - 6144) - 12288) \\
    g_4 & = \frac{32768}{2} \left( e (e (330 e + 405) + 480) + 480 \right) \\
    g_6 & = \frac{8192}{4} \left( e (-14805 e - 13440) - 8960 \right) \\
    g_8 & = \frac{786432}{6} \left( e (630 e + 315) \right) \\
    g_{10} & = \frac{131072}{8} \left( e (693 e) \right)
    \end{align*}
\]
equation for LATITUDE B as a function of RECTIFYING LATITUDE u
B = u + G2*sin(2u) + G4*sin(4u) + G6*sin(6u) + ...

\[
\begin{align*}
G & = \frac{20861}{2} + \frac{255}{524288} + \frac{213}{4096} + \frac{3}{2048} + \frac{3}{16} + \frac{3}{8} \\
& = \frac{197}{2} + \frac{533}{4096} + \frac{21}{2048} + \frac{21}{16} + \frac{21}{8} \\
& = \frac{4096}{4} + \frac{8192}{8192} + \frac{256}{256} + \frac{256}{256} \\
& = \frac{131072}{10} + \frac{4096}{8} + \frac{6144}{8} \\
& = \frac{1097}{8} + \frac{1097}{131072} \\
& = \frac{65536}{10} + \frac{131072}{8} \\
& = \frac{8011}{10} + \frac{2621440}{8} \\
\end{align*}
\]

coefficients in Horner form

\[
\begin{align*}
G & \approx \frac{2}{e} + \frac{2}{e^2} + \frac{2}{e^3} + \frac{2}{e^4} + \frac{2}{e^5} + \frac{2}{e^6} + \frac{2}{e^7} + \frac{2}{e^8} \\
& = \frac{524288}{4} + \frac{8192}{6} + \frac{394}{8} + \frac{15057}{10} + 8011 \\
\end{align*}
\]
